Running Windows Portable - Core

Download Unimus

Unimus for Windows is available in 2 versions:

- Standard installer
- Portable (standalone)

Download link:
https://unimus.net/download.html

For information on installing Unimus, please see this wiki article.

Portable

You can run Unimus Core in portable (standalone) mode - you simply launch it, and it runs.
This means there is nothing to install, and the Core will only run when you launch it yourself.

Install Java

Before running Core, you will need to install Java.
Unimus Core is written in Java, and requires a JRE (Java Runtime Environment) to run.
We support Java 8-11, and you can use Oracle, OpenJDK or Corretto JRE.

After installing Java, Java may launch your browser and attempt a browser plugin test - you can safely ignore this.
Unimus Core does **not** use Java in the browser (the Core is **not** an Applet), so this functionality is not required.

Run Unimus Core Portable

Before running the portable Core, you will need to create the config file manually.

Please create the file in: **C:\ProgramData\Unimus-Core\unimus-core.properties**

```
unimus.address=some.server.address
unimus.port=5509
unimus.access.key=really_long_access_key_from_the_zone_of_this_core
```

After the config file is in place, run the portable Core by launching the Unimus-Core.exe.
The Core should start, and you should see your Core online in Unimus.

The Core is running in a command-line window when running in Portable (standalone) mode.
As long as this window remains open, the Core will stay running.

You can close the Core simply by closing the command-line window (or use Ctrl+C).
